**Abstract:** Bio-based fertilizers (BBFs) can be a solution for converting agricultural waste into new products useful for increasing organic matter in the soil, thus reducing the consumption of mineral fertilizers. This can contribute to the ecological transition launched by the European Commission for the coming decades. Scenario analysis is an effective tool to assess the factors that can affect the development of the agri-food supply chain, evaluating the effects of their possible evolutions.

The aim of this work is to draw plausible future scenarios for the BBF supply chain and to strengthen the consistency evaluation process of these scenarios. We built the scenarios considering both the literature and findings from stakeholder consultations. We then verified their consistency by adopting the Cross-Impact Balances (CIB) method, along with other techniques to better evaluate the consistency and plausibility of the narratives.

The analysis provides stakeholders with information to evaluate possible future trends in the BBF supply chain. Monitoring the evolution of the identified drivers and maintaining constant and periodic discussions among stakeholders constitute the prerequisites for supporting the desirable future development of BBFs.

## 1. Introduction and backgrounds

In an increasingly globalized and interconnected world, the development of socio-economic systems is influenced by a multitude of factors whose trends are difficult to predict, at least in the long term. As demonstrated by recent financial, pandemic, and climate crises, mathematical models are not always capable of producing reliable forecasts in a context where uncertainty plays a determinant role (Puy et al., 2022). The most recent big-data analysis tools and the development of artificial intelligence will certainly enhance our ability to understand the world, but they will also generate a mass of results that are not always coherent, making it difficult to identify the most reliable ones (Hariri et al., 2019). Chaos theory has demonstrated the unpredictability of complex systems, where a small change in the state of one or more factors is sufficient to produce completely different effects (Schueler, 1996).

Future scenario analysis does not aim to predict the future but evaluates what happens if one or more factors that influence the system (driving forces) evolve in certain directions. It is not a probabilistic model but a logical approach for identifying possible evolutionary trends based on an appropriate knowledge of the initial state of the determining factors, the cause-effect relationships between them, and their impacts on the system.

There is no single definition of scenarios. In this work, scenarios are plausible narratives of how the future could develop, based on a coherent and consistent set of assumptions about the main driving forces and their relationships (Hunt et al., 2012; Boschetti et al., 2016; Guivarch et al., 2017). The narratives or storylines focus on the drivers that have greater importance and uncertainty, highlighting the main scenario characteristics, the relationships between key driving forces, and the dynamics of

50 their evolution (IPCC, 2014). They may include quantitative data from literature, specific surveys, or  
51 mathematical models (Swart et al., 2004; Reed et al., 2013; Guivarch et al., 2017).

52 The literature on future studies is extensive, with several attempts at classification tracing back to the  
53 triad of possible, probable, and preferable futures. Börjeson et al. (2006), adapting previous  
54 classifications, distinguish three main categories of scenario studies based on the user's perspective  
55 (questions): predictive scenarios (what will happen?); exploratory scenarios (what can happen?); and  
56 normative scenarios (how to reach a preferred future situation?), further articulated based on more  
57 specific questions.

58 Different techniques can be adopted to develop future scenarios. A widespread method generates four  
59 alternative (exploratory) scenarios related to the investigated topic using the 2x2 Matrix Technique  
60 (Schoemaker, 1995; O'Neill et al., 2014; Rhydderch, 2017; Fritsche et al., 2021). For this purpose,  
61 two factors of great importance and uncertainty that influence the future of the topic are identified,  
62 with two opposed outcomes imagined for each. Placing the two factors on a Cartesian plane, they  
63 intersect at the present time to form four quadrants, with the ends of the axes indicating the possible  
64 evolution of the two factors at the chosen future horizon. Each quadrant produces a scenario whose  
65 narrative is determined by the outcomes of the factors on the axes and other relevant identified factors.

66 Another technique of interest is a normative scenario, participatory backcasting (Quist and Vergragt,  
67 2006), which starts from sharing a desirable future among stakeholders and identifies possible actions  
68 (policies) that may lead to the fixed goal. Explorative scenarios and backcasting can also be  
69 combined, as Vervoort et al. (2014) experimented in the context of food security.

70 Numerous public and private institutions use scenario analysis for their strategic choices and policies.  
71 In some governments, it has become an institutionalized activity (as in Singapore, the United  
72 Kingdom, and Finland) (Störmer et al., 2020). The European Commission (EC) has also been using  
73 this tool for a long time. Burgelman et al. (2014) trace its history, noting that the motivation behind  
74 this choice was to improve the administration and governance of the EC through the broad  
75 involvement of stakeholders in the decision-making process. The use of foresight processes by the  
76 EC began in the late 1970s, but only in 2017 did the EC produce documents officially acknowledging  
77 the usefulness of foresight for better regulation (Störmer et al., 2020). The EC documents cited  
78 recognize four functions or benefits of applying foresight to policymaking: informing policy,  
79 facilitating policy implementation, embedding participation in the policymaking process, and  
80 supporting policy definition.

81 Scenario analysis has constituted an important tool for the scientific community in defining possible  
82 future paths of socio-economic development, both globally and in specific sectors and territories.  
83 Among the former, a series of future scenarios have been produced, starting from the conceptual work  
84 of O'Neill et al. (2014) and later defined in the corresponding narrative contents (O'Neill et al., 2017).  
85 These are known as Shared Socioeconomic Pathways (SSPs) and describe alternative future  
86 trajectories of several factors connected to the challenges that climate change poses to society  
87 concerning adaptation and mitigation. They represent plausible conditions that can be realized in the  
88 future (to 2050) in large regions of the world regarding human and demographic development,  
89 economy and lifestyle, policies and institutions, technology, environment, and natural resources.

90 Due to the general nature of the SSPs, they can be used as references for other analyses of  
91 development paths, both on issues directly related to the climate and on more specific themes, at both  
92 global and sub-national scales (e.g., Lassaletta et al., 2019; Chen et al., 2020; Mitter et al., 2020), thus  
93 distinguishing basic and extended SSPs (O'Neill et al., 2014; van Ruijven et al., 2014). Using SSP  
94 narratives, Mitter et al. (2020) defined possible future scenarios for the European agri-food system,  
95 the so-called EUR-Agri-SSPs, providing plausible references to derive storylines related to more  
96 specific contexts (sectors or areas). The EUR-Agri-SSPs have recently been used as a reference for  
97 defining future scenarios for pesticides (Nagesh et al., 2023).

98 Using the same context scenarios, in this work we define plausible future development pathways for  
99 the bio-based fertilizer value chain, identifying the main factors that can influence its future  
100 development.

101 To date, there is no unique definition of bio-based fertilizers (BBFs), but work is underway at the  
102 European level towards a standard definition (ESPP, 2023). Wester-Larsen et al. (2022) define BBFs  
103 “as materials or products derived from biomaterials (plant, animal, or microbial origin, often wastes,  
104 residues or side-streams from agriculture, industry, or society) with a content of bioavailable plant  
105 nutrients suitable to serve as a fertilizer for crops” (Wester-Larsen et al., 2022, p.1). This is the  
106 meaning of BBFs used in our work, which is consistent with the elements of the ongoing debate at  
107 the European level and the recent literature on the subject (Tur-Cardona et al., 2018; Chojnacka et  
108 al., 2020; Puglia et al., 2021; Egas et al., 2023; Kurniawati et al., 2023).

109 The cited literature reports how the production of bio-based fertilizers from residues and by-products  
110 of the agri-food system would contribute to solving the problems arising from the large quantities of  
111 organic waste produced and the use of mineral fertilizers, which depend on non-renewable resources.  
112 An increasing and widespread use of BBFs to replace mineral fertilizers would improve the health of  
113 natural resources by reducing the accumulation of nutrients in the soil and water. The recovery of  
114 useful materials from the waste of the agri-food system to produce fertilizers also responds to the  
115 need to make the entire system more sustainable. This need was expressed by the European  
116 Commission in the Circular Economy Action Plan (European Commission, 2015), most recently  
117 updated (European Commission, 2020), and is reiterated by the 2019 EU Fertilizer Regulation  
118 (European Commission, 2019), as well as the recent report from the European Environment Agency  
119 (2020). However, it should be considered that the use of these products is not free from problems in  
120 the current state of technology. It has been ascertained that contamination by heavy metals and  
121 pathogens represents the main problem for the use of BBFs, whose acceptability by consumers  
122 (farmers) would be hindered, among other things, by issues relating to costs (for transport and  
123 production) and the still unclear political framework (Kurniawati et al., 2023).

124 For the purposes of this work, the qualitative data for identifying the most important and uncertain  
125 driving forces relating to BBFs were provided by a multi-actor participatory technique. This approach  
126 was supported by data collection from official sources and literature.

127 Stakeholder engagement is quite common in futures studies. In the review by Fauré et al. (2017), they  
128 highlight how this approach is particularly prevalent when dealing with issues related to  
129 sustainability. More generally, Perna (2017) points out that anticipating the future requires more  
130 interdisciplinary and multi-perspective collaboration due to the growing complexity in our societies.  
131 The participatory approach strengthens scenarios and facilitates the activities of researchers, policy  
132 makers, and decision-makers (Borch and Merida, 2013; Mitter et al., 2020).

133 The participation of stakeholders also contributes to ensuring the internal consistency of the storylines  
134 (or grading them in terms of coherence) through the judgments expressed by experts on the  
135 relationships between the identified drivers. A tool to visualize these relationships is Causal Loop  
136 Diagrams (CLD), used, for example, by Mathijs et al. (2017) and Mitter et al. (2020). In this work,  
137 we adopt the Cross-Impact Balance (CIB) analysis (Weimer-Jehle, 2006), which identifies internally  
138 consistent scenarios through cross-impact matrices. More generally, the CIB method is aimed at the  
139 "systematic construction of qualitative and semi-quantitative scenarios" (Weimer-Jehle, 2023), and  
140 has been applied in many contexts to analyse the relationships between the factors of scenarios using  
141 an algorithm. In the literature, CIB has more frequently been used for the analysis of scenarios in the  
142 energy field, for climate change, and for sustainable development. There are few works about the  
143 agricultural and agri-food sector, with only one publication (Kurniawan, 2020) that used CIB together  
144 with the SSP method to evaluate the coherence of scenarios at different scales of detail. In our  
145 analysis, we adopted CIB to evaluate the consistency of scenarios of the same scale, constructed  
146 through the SSP method (BBFs scenarios).

147 In summary, the aim of the work is twofold. Firstly, it is intended to draw plausible future scenarios  
148 for the BBF supply chain, and secondly to verify whether CIB can be used to facilitate the consistency  
149 analysis of the scenarios, reducing the risk of outlining internally inconsistent situations. The  
150 originality of this work concerns both the study object of the scenario analysis (BBF supply chain)

151 and the combined use of CIB and EUR-Agri-SSP methodologies to strengthen the validation process  
 152 of the scenarios.

153 In the following paragraphs, the methodological path adopted to build plausible and consistent future  
 154 scenarios for BBFs is described, followed by the achieved results. The discussion is focused on the  
 155 combined use of different methods and tools. Finally, the advantages and limitations of the  
 156 methodological approach are outlined in the conclusion.

157

## 158 2. Methodology

159 The methodology used to build the BBF scenarios is based on two preliminary considerations.

160 First, the case study represents a segment of the agri-food chain, which is itself a component of the  
 161 agri-food system. This concatenation of contexts, which can be further expanded to include higher  
 162 levels, implies that the driving forces influencing the development of BBFs can be internal to the  
 163 sector or derived from external contexts. For example, the production cost of BBFs or their chemical-  
 164 physical characteristics are internal drivers, while the prices of mineral fertilizers or the  
 165 environmental sensitivity of consumers are external factors. The ability of the SSPs to nest scenarios  
 166 allows for the linking of external factors to internal ones, thereby articulating higher-level narratives  
 167 by incorporating specific insights and variations for the analysed sector.

168 The second consideration concerns the role of the multi-actor approach. Generally, building scenarios  
 169 with the participation of stakeholders involves a lengthy process of exchanges with the actors,  
 170 including a preparatory phase and multiple meetings in which the elements of the scenarios are  
 171 progressively defined (e.g., Bock et al., 2020; Mitter et al., 2020). In our study, the approach was  
 172 decidedly more concise, hampered by the restrictions linked to the COVID-19 pandemic. Due to these  
 173 constraints, the participatory process was carried out through online workshops and surveys, an  
 174 approach that limited the interaction between the subjects involved but sped up the collection of  
 175 information.

176 The analysis followed the steps shown in Table 1.

177 **Table 1 - Synoptic diagram of the analysis path**

178

179

### 2.1. *Identifying and analyzing the focal issue*

180

The case study focuses on the production and use of BBFs, considering the main aspects that can affect the organization and development of this supply chain. The goal was to outline some plausible and alternative scenarios for 2050, useful to support decision strategies for both those who want to invest in the sector and policymakers who intend to facilitate the development of BBFs.

184

An analysis of the available documentation focused on the fertilizer sector (Chojnacka et al., 2020; Fertilizers Europe asbl, 2021) and more generally on the development of the agri-food system (FAO, 2022) has provided the first qualitative and quantitative information. We classified this information according to the STEEP categories (society, technology, economy, environment, politics). For each category, the phenomena that characterize the sector have been summarized, with statistical and forecast data, to evaluate the current and prospective situation. In this way, the main factors (driving forces or drivers) to be considered for the development of BBFs were identified.

190

191

### 2.2. *Choosing the appropriate scenario building method*

192

The definition of plausible future scenarios for BBFs started with the identification of more general scenarios for the food system and the main factors that influence its evolution. To this end, academic and grey literature and research projects on the subject were examined via the web, and also retrieved from the websites of international organizations, government agencies, and private institutions. The H2020 SURE-Farm Project was identified as consistent with our objectives. SURE-Farm defined the EUR-Agri-SSPs scenarios (Mathijs et al., 2017, also described in detail in Mitter et al., 2020), which are derived from the global Shared Socioeconomic Pathways (SSP) scenarios (O'Neill et al., 2017). Mitter et al. (2020) start from the SSPs to narrate the future conditions of the farming system in Europe and use a multi-actor approach for their definition. They extend the analysis to food consumer issues and use other scenario studies to enrich the narratives. Based on the uncertainty of the main socio-economic, environmental, and technological factors, they define five alternative scenarios, the EUR-Agri-SSPs, describing plausible future conditions (up to 2050) for the European agricultural and food systems in relation to climatic challenges.

205

The EUR-Agri-SSPs are taken as context scenarios for the BBFs case study. Each of them defines differentiated conditions of the macro-environment (population, geopolitics, economic development, markets, technology, etc.) which in turn influence the conditions of the specific factors identified for the development of the BBF supply chain. In this study, only four of the five EUR-Agri-SSPs have been considered, excluding the EUR-Agri-SSPs No. 2 because it has intermediate characteristics compared to the other scenarios.

210

211

### 2.3. *Identifying the drivers and organizing the information framework*

212

The set of indicators that measure the possible trends of the drivers in the reference period of the scenarios has been defined. This information, organized by STEEP categories, formed the basis of the BBFs scenarios, built on differentiated trends and therefore outlining evolutionary trajectories that lead to alternative or opposite future situations. In this way, it was possible to evaluate which factors determine the preferable evolution of BBFs.

217

The set of drivers selected for the BBFs scenarios derives from the bibliographic survey (Phase 1) and the participatory process, and partially from those already identified by Mitter et al. (2020) for the EUR-Agri SSP scenarios. The main driving forces that can favour or hinder the development of fertilizers of biological origin in the European agri-food system were identified and discussed in several meetings coordinated by the research group, in which sector stakeholders participated.

222

For this purpose, in each of the European areas considered for the development of the case study (Almeria (ES), Flanders (B), Friuli-Venezia Giulia (IT), and Pays de la Loire (FR)), 10-15 stakeholders from the fertilizer sector were selected, including researchers, operators, associations,

224

225 and policymakers, based on the following criteria: Interest, Availability, Relevance, Appropriateness,  
226 Representativeness, Broad Vision (Zawalińska et al., 2022).

227 The four regions were selected by the Rustica project partners because the agricultural sector  
228 significantly contributes to the deterioration of natural resources, although to different extents. The  
229 intensity of agricultural production causes widespread contamination by fertilizers (and pesticides),  
230 and considerable quantities of low-quality waste pose problems for their proper utilization/disposal,  
231 risking worsening the environmental impact. Despite local policies promoting the development of the  
232 circular economy, the use of food sector waste in the form of bio-based fertilizers is still rather limited  
233 in all regions, as results from the direct survey carried out during the EU Rustica Project. The diversity  
234 of the socio-economic contexts of the regions, through the multi-actor approach, provided elements  
235 to enrich and strengthen the prospective framework defined hereafter in the BBFs future scenarios.  
236 Having been informed in advance about the objectives and contents of the study, the stakeholders in  
237 each area were then invited to participate in a workshop during which they were interviewed based  
238 on a work outline common to all areas. Overall, around 50 stakeholders were involved to identify and  
239 classify the most relevant and uncertain drivers of the BBF supply chain. Relevance was assessed by  
240 the power to influence the evolution of the phenomenon of interest (BBFs development), while  
241 uncertainty concerned the predictability of the trend in the period considered. At the end of the  
242 stakeholder consultation, 134 of the most relevant and uncertain factors were considered for the  
243 scenario analysis (Table A in the appendix). These factors were further analysed to classify them  
244 according to their common characteristics in terms of context and/or purpose. This slightly more  
245 detailed reclassification of the STEEP categories was helpful in identifying these seven main driving  
246 forces: sustainability awareness, political framework, fertilizers market, technological solutions,  
247 innovation uptake process, agri-environmental system, and bioeconomy patterns. These were  
248 considered the main determinant factors for the evolution of BBFs.

#### 249 **2.4. Building and analyzing scenarios**

250 The BBFs scenarios were developed by associating the drivers identified for the BBFs with the EUR-  
251 Agri-SSP context scenarios. The process of adapting and deepening context scenarios into BBFs ones  
252 was long and articulated. In continuity with the context scenarios, the drafts of the BBFs narratives  
253 were elaborated, assuming four distinct future situations: two extreme and opposite  
254 (favourable/unfavourable for the BBFs development) and two with a mix of positive and negative  
255 elements (Phase 4). A fifth EUR-Agri-SSP scenario was not considered as it is intermediate between  
256 the others. In the first two scenarios, the direction of the drivers is opposite, all aimed at facilitating  
257 or hindering the occurrence of a positive context for BBFs, while the other two are characterized by  
258 diversified situations with some dominant evolutionary elements.

259 Each scenario is characterized by a different evolution of the drivers. For example, in the first  
260 scenario, the sustainability of agriculture is favoured by a growth in social environmental awareness,  
261 which implies a propensity to reuse agricultural waste and to eat healthier food.

262 The drafting of a scenario narrative is rigidly codified in the literature, and although there are margins  
263 for subjective interpretations, these must be based on objective elements such as the possible  
264 evolutions of coherent and specific drivers. The subjectivity of the interpretation can only make the  
265 narrative more interesting by avoiding a slavish commentary on the situations that outline the  
266 scenario. Nevertheless, the guidelines of the methodology adopted, the feedback from the experts,  
267 and the robustness check of scenarios limit the personal influences of researchers, experts, and  
268 stakeholders.

#### 269 **2.5. Checking the consistency of BBF scenarios**

270 With the drafting of the final narratives, the analysis of the scenarios was not concluded, as it was  
271 necessary to verify that the construction and revision process had not led to inconsistent situations  
272 within each scenario and between them. For example, if a scenario considers a sharp increase in  
273 energy prices and at the same time a reduction in the prices of mineral fertilizers, a contradictory or  
274 at least unrealistic situation has occurred.

275 We then proceeded with a consistency check of the BBFs scenarios by analysing the relationships  
276 and combinations between the states of the drivers. While Mitter's methodology used Causal Loop  
277 Diagrams (CLD) to analytically describe the interdependencies between factors, another analysis tool  
278 called Cross-Impact Balances (CIB) (Weimer-Jehle, 2006) was chosen for BBFs. Both methods  
279 analyse the relationships of influence between drivers and are used when it is not possible to adopt a  
280 mathematical model to measure these interdependencies. The CIB method analyses the relationships  
281 between the factors through a quantitative assessment (scores), while the CLD uses a graphic  
282 language (flow charts). The CLD method should be applied to each hypothesized scenario, while the  
283 CIB method considers all possible scenarios generated by the drivers' combinations. For this reason,  
284 CIB was chosen to assess all scenarios, including those unrelated to Mitter's results.  
285 The CIB method is based on the construction of a symmetrical matrix where the different future  
286 situations are placed by row and by column. These situations are identified by a title (descriptor) and  
287 articulated into a few possible evolutionary paths (variants). The descriptors summarize the  
288 previously identified drivers, which act in the same context, labelling the group with a title evocative  
289 of the dominant theme, while the variants are derived from the different evolutions of the drivers  
290 between the scenarios.

291

### 292 **3. Results and discussion**

#### 293 **3.1. *The future scenarios for the bio-based fertilizers***

294 Following the methodology described above, the first draft of the BBFs narratives was prepared by  
295 the research group and submitted for review to a panel of experts. Twelve experts from different  
296 institutions and professional backgrounds participated in the panel. The online focus group was held  
297 in July 2021. The participants were selected based on their roles and expertise in the field:  
298 Research/Academics, Stakeholders, and Policymakers.

299 Two experts were from The University of Bologna and CREA Agriculture and Environmental  
300 Research Centre, with technical backgrounds in fertilizers and organic farming. A representative from  
301 ENEA had expertise in biomass for energy use, and a fruit supply chain expert was from CRPV. The  
302 six stakeholders involved included representatives from the Italian Biomass Association – ITABIA,  
303 the President of the Associazione Chimica Verde Bionet-Biomass and Green Chemistry, a  
304 representative from Esco Lazio - Biogas and Digestate, a biological expert in biofertilization from  
305 BIO/INTESA, the Head of Communication for Terre d'Etruria Cooperative, and a representative  
306 from Enomondo, which focuses on the recovery of agri-food waste for bioenergy and compost.  
307 Additionally, two experts from the Italian Ministry of Agriculture and three agri-environmental  
308 technicians from three Italian regions were involved.

309 They were asked to evaluate the narratives' plausibility, consistency, richness, creativity, and  
310 salience, as indicated by the reference methodology (Mitter et al., 2020). These criteria aim to  
311 consolidate the texts by eliminating any inconsistencies and evaluating their degree of realism while  
312 maintaining elements of creative originality, considering unexpected and improbable situations. This  
313 is exemplified by the war in Ukraine, an extreme event not directly considered in the hypothesized  
314 scenarios, which were developed before the conflict, although one scenario describes a situation of  
315 strong territorial inequalities and social conflicts.

316 The experts' suggestions were useful in refining the narratives and arriving at their final version, the  
317 summary of which is reported below, while their full version is available online as supplementary  
318 material. Each of the following narratives is composed of the main elements of the context scenario  
319 (from Mitter et al., 2020, in a box in italics) and the extended BBFs narrative (in regular font).

#### 320 **FIRST SCENARIO: BBFs ON VALORIZATION PATH**

321 *Main elements of context scenario: Agriculture on sustainable paths*

322 *A strong network of small and medium-sized towns and large cities. Diversity in agricultural supply chains*  
323 *supported by globally connected markets with internalized costs of trade. Multi-level cooperation, policy*  
324 *integration, and societal participation. Pronounced technological development directed towards*

325 *environmentally friendly processes and cooperation between farmers and consumers. Increasing*  
326 *environmental awareness, resource use efficiency, and environmental health.*

327 **BBFs narrative**

328 Sustainability awareness is growing in agriculture, leading to the adoption of circular business models, often  
329 through vertical integration in supply chains. Growing urbanization facilitates the recovery and enhancement  
330 of biomass, thanks to infrastructure and the concentration of actors and knowledge in cities. Digital  
331 technologies ensure the dissemination of knowledge to the most remote rural areas, where technological  
332 solutions are also widespread.

333 There is a growing demand for safe and sustainable (organic) products, especially local products. Society's  
334 interest in food production methods directs agriculture towards more sustainable techniques and, due to strict  
335 environmental legislation, towards greater use of bio-based products from agricultural waste, such as  
336 fertilizers. This leads to competition between the possible destinations of raw materials, resulting in wide  
337 price volatility for bio-based products.

338 With the increase in demand for bio-based products, the supply is organized and structured into small or  
339 medium-sized networks with consortium-type biomass transformation plants spread throughout the territory,  
340 depending on the availability of local feedstock. Sustainable logistics allow for efficient biomass collection  
341 and delivery services. Within the local networks, integrated products and services adapted to the needs of  
342 farms are provided.

343 Policy encourages and supports the adoption of circular business models by stimulating the integration of  
344 actors. On the demand side, policy pays great attention to communication and fosters relationships based on  
345 trust.

346 The integration between economic subjects facilitates the adoption of technological innovations that improve  
347 the quality of the BBFs (stability of characteristics, ease of use, effectiveness). Artificial Intelligence (AI)  
348 caters to fertilization needs by powering Decision Support Systems (DSS) based on the automatic exchange  
349 of data between devices and BBFs suppliers.

350 The greater use of BBFs derived from the recycling of fruit and vegetable waste reduces the utilization of  
351 mineral fertilizers, avoiding the exploitation of non-renewable resources for their production.

352 **SECOND SCENARIO: BBFs ON DIFFERENTIATION PATH**

353 *Main elements of context scenario: Agriculture on separated paths*

354 *Decelerated urbanization. National agricultural supply chains benefit from protectionism. National*  
355 *agricultural policies aim for national food and energy security. Slow agricultural technology development*  
356 *and uptake due to reduced investments and scepticism. High pressure on natural resources due to high*  
357 *national demand for agricultural commodities and limited coordination and technological progress.*

358 **BBFs narrative**

359 A general climate of mistrust, slow generational turnover, and the degradation of infrastructure hinder the  
360 integration of economic actors and the adoption of innovative and eco-sustainable solutions. Society also  
361 lacks a culture of waste recycling.

362 Low environmental sensitivity creates an unfavourable climate for the spread of sustainable (organic)  
363 agriculture and the adoption of circular production processes, which are also hampered by the reduction of  
364 public support. At the farm level, the valorisation of waste is limited and often faced with ineffective  
365 techniques. This hinders the spread of bio-based productions, to which inefficient logistics contribute. Even  
366 if the price of biomass is low, the final bio-based product does not have a good quality-price ratio.

367 A few large producers of fertilizers (mostly mineral fertilizers) dominate the market, while the growing  
368 isolation of countries makes access to raw materials (such as phosphorus) more difficult and contributes to  
369 their price increase. The large companies cater to their country's fertilizer needs, increasing their use  
370 efficiency through customized solutions and new technologies for mineral extraction.

371 Environmental policy is inconsistent and unresponsive, and the bioeconomy and circular economy languish  
372 due to the closure of national economies and the lack of environmental objectives. Traditional agricultural  
373 lobbies, dominated by a few major players, increase their influence on political decision-makers, while the  
374 integration of local actors to organize integrated supply chains is not supported by adequate regional policies.

375 The scarcity of investments in R&D limits the development of technologies with low environmental impact.  
376 There is also a lack of technological solutions for the adequate reuse of agricultural waste. This leads to poor  
377 quality finished products, which therefore cannot compete with mineral fertilizers. Small-scale plants are

378 present only in some areas with strong production specialization, but their diffusion is hindered by general  
379 mistrust and difficulty in establishing relationships.  
380 On the environmental front, the inappropriate treatment of agricultural residues contributes to the pollution  
381 of natural resources.

### 382 **THIRD SCENARIO: BBFs ON POLARIZATION PATH**

383 *Main elements of context scenario: Agriculture on unequal paths*

384 *Territorial fragmentation. A business-oriented elite dominates agricultural supply chains. A business-*  
385 *oriented elite dominates European institutions and sets the policy agenda. Rapid technology development*  
386 *focuses on production and energy efficiency. Environmental awareness is limited to the neighbourhoods of*  
387 *the wealthy upper class.*

### 388 **BBFs narrative**

389 The tendency towards individualism hinders the organization of supply chains, while the lack of  
390 environmental sensitivity means that sustainable techniques remain confined to some rural areas and  
391 communities. In these areas, the lack of infrastructure produces serious logistical problems for the transport  
392 and storage of agricultural products, as well as for the distribution of inputs and the collection of production  
393 waste.

394 Only in peri-urban areas do a few fertilizer producers invest in bio-based products to differentiate their supply  
395 and respond to an elite demand willing to pay high prices. As a result, BBFs are more expensive than mineral  
396 fertilizers due to the absence of a market or well-structured supply chain. Furthermore, economic conditions  
397 do not support farmers adopting high-cost inputs due to low food prices.

398 The demand for bio-based fertilizer products is weak as environmental standards are not restrictive. This  
399 situation is also exacerbated by the lack of specific regulations on the use of organic waste. Existing  
400 regulations, which are neither coherent nor incisive, favour aspects of technological development over those  
401 of environmental sustainability. The main rules that define certifications and labels are managed and  
402 guaranteed by private bodies, leading to differences between territorial productive systems.

403 Subsidies for innovative technologies in agriculture favour investments only in the most developed  
404 regions/countries, where effective BBF technologies are adopted. Elsewhere, the complexity and cost of  
405 technology limit its local accessibility. Technological platforms interconnect economic actors mainly to  
406 manage trade flows while maintaining the managerial autonomy of companies.

407 In general, agriculture contributes to the degradation of natural resources, as the use of mineral fertilizers and  
408 chemical pesticides is intensive. Sustainable agriculture methods and circular approaches are widespread  
409 only in natural areas. Here, the use of bio-based fertilizers is mandatory as agricultural products are certified  
410 and subject to strict quality controls.

### 411 **FOURTH SCENARIO: BBFs ON TECHNOCRATIC PATH**

412 *Main elements of context scenario: Agriculture on high-tech paths*

413 *Metropolization. High-tech, large companies dominate globalized agricultural supply chains. European*  
414 *institutions foster international trade but delay environmental action. There is a high affinity for output-*  
415 *oriented technology. A lack of global environmental awareness.*

### 416 **BBFs narrative**

417 The environmental awareness of the population and young farmers is limited, partly because the high and  
418 generalized orientation towards using technology for all aspects of life has solved many problems related to  
419 the scarcity of non-renewable resources. However, in rural areas excluded from technological development,  
420 traditional agricultural practices remain inefficient and sometimes negatively impact natural resources.

421 Food waste is concentrated in cities due to increasing urbanization. Bio-based fertilizers are processed in  
422 agro-industrial districts where the plants operate on an industrial scale and are part of multinational networks.  
423 Waste from agricultural production in less urbanized areas is recycled by large high-tech farms through their  
424 own small and medium-scale plants. The mineral fertilizer industry dominates the market thanks to the  
425 development of more efficient technologies and highly effective formulations. Green chemistry is developing  
426 rapidly, but the technologies are protected by patents and are therefore not very accessible due to the  
427 competitive market environment.

428 Public support for the circular approach is almost absent, with most investments being private. In agri-food  
429 supply chains, processing waste is usually recycled to improve efficiency. Policies supporting bio-based  
430 production are oriented towards their technological uses (e.g., bioplastics for food packaging). Specific

431 legislation for bio-based fertilizers is lacking, but some available measures concerning labels facilitate  
 432 communication to consumers (health footprints).  
 433 Internet of Things (IoT) and Blockchain technologies allow the automated management of a well-integrated  
 434 and traceable agri-food chain, where biomass for recycling is also managed. In this way, bio-based waste and  
 435 fertilizers are valorised. However, mineral fertilizers dominate the market due to the presence of large  
 436 companies and pressure from lobbies.  
 437 The lack of environmental awareness leads to negligent management of natural resources in agriculture. In  
 438 peri-urban areas, the intensive use of pesticides and inorganic fertilizers creates problems with dangerous  
 439 residues from chemical inputs. The production and use of bio-based fertilizers are quite widespread but  
 440 limited due to competition with fossil-based inorganic fertilizers.

441 **3.2. The consistency of the scenarios**

442 The next step was the validation of the robustness of the scenarios through the CIB analysis. The CIB  
 443 matrix (Table 2) developed for the BBFs is made up of seven descriptors and three variants each. The  
 444 resulting matrix is sized at 21 rows by 21 columns, filled with scores assigned by the research group,  
 445 evaluating the direction of each interdependence between the variants. The CIB method can use  
 446 different scoring (e.g.,  $\pm 3$ ) to measure the strength of relationships. Usually, the score is an integer  
 447 value between -1 and 1, which indicates whether the situation indicated in the row favours (1) or  
 448 hinders (-1) the one indicated in the column. The zero value indicates substantial neutrality, while the  
 449 null value indicates the absence of interdependence between the two situations.

450 **Table 2 - CIB matrix for the BBFs scenarios**

Descriptors and variants	A			B			C			D			E			F			G		
	1	2	3	1	2	3	1	2	3	1	2	3	1	2	3	1	2	3	1	2	3
<b>A. Innovation uptake process</b> 1. Linear transfer 2. Cooperative participation 3. Selfish approach													-1	1	0						
<b>B. Sustainability Awareness</b> 1. Societal rooted 2. Consumers driven 3. Elite fashion							1	1	-1	1	0	-1	1	0	-1	1	1	-1	1	1	-1
<b>C. Bioeconomy development</b> 1. Circular based 2. Transition in progress 3. Business as usual				1	0	-1				1	1	-1	1	0	0				1	0	-1
<b>D. Fertilizers Market</b> 1. Bio-based competitiveness 2. Niche productions 3. Inorganic power							1	-1	0							1	0	-1	1	1	-1
<b>E. Agri-environmental System</b> 1. Agroecological approach 2. Low impact standards 3. Sustainable oasis				1	0	0	1	1	-1							1	0	-1	1	0	-1
<b>F. Political Framework</b> 1. Systemic regulations 2. Environmental compliance 3. Chemical lobbies	0	1	0	1	0	-1				1	0	-1	1	0	-1				1	1	-1
<b>G. Technological Solutions</b> 1. Accessible and effective 2. Effective but complex 3. Efficient but ineffective	0	1	0	1	0	-1	1	0	-1	1	0	-1	1	0	1	1	1	-1			

451 Source: own elaboration

452 The CIB algorithm computes the algebraic sum of the scores of all the matrix combinations and  
 453 considers more coherent scenarios when positive values prevail over negative ones. These are the  
 454 scenarios that do not present contradictions between the different hypothesized situations. The  
 455 number of consistent scenarios varies according to the scores assigned and can be very high if the  
 456 interdependence relationships generate many possible combinations or even null if they outline  
 457 alternative and non-overlapping situations. This methodology was used to evaluate whether the four  
 458 hypothesized BBFs scenarios fall within the set of possible coherent scenarios.  
 459 The software application of the CIB algorithm extracted nine consistent scenarios with positive scores  
 460 from 2,187 variants combinations. These scenarios were compared with the BBFs ones to assess  
 461 correspondences and differences. Table 3 indicates the variants that characterize the scenarios

462 identified by the CIB. Those inside the green columns coincide with the situations described in the  
463 BBFs narratives. In summary, the CIB analysis confirmed that the BBFs scenarios are consistent as  
464 no contradictions emerge in the relationships between the drivers considered.  
465 The CIB analysis also identified five more scenarios in addition to those derived from the SSP  
466 methodology. These are situations that differ in a few elements from BBFs narratives but are equally  
467 plausible.

Source: own elaboration

470 From the synoptic Table 2 of the CIB scenarios, it also emerges that some situations (variants) that  
 471 are not particularly favourable to the development of BBF are more frequent. In the other scenarios  
 472 identified by the CIB, the influence of chemical lobbies (F3) and the persistence in the market of  
 473 mineral fertilizers (D3) are recurring variants, probably due to the setting of low environmental  
 474 standards (E2). Technological processing is not efficient and is not equally capable of creating  
 475 effective and valid BBFs (G3). The ecological transition process is unfinished (C2), and the  
 476 production of BBF is still marginal and valued only within some social contexts (B3); the  
 477 development of innovations is weak and individualistic (A3).  
 478 The CIB tool also provides a graphical representation of the influence force of descriptors. In the  
 479 following graph (Figure 1), the descriptors in the upper right quadrant are the most influential,  
 480 meaning they determine the status of the other factors the most.

481 **Figure 1: Influence profile of drivers**

482 Source: own elaboration  
 483 Technological solutions are the most influential factor (high active score sum), while the innovation  
 484 process is the least influential. This result is probably affected by the presence during participation  
 485 processes of several people with technical skills who therefore emphasized the relevance of the  
 486 technological drivers for the development of BBFs. Social awareness and the political context are  
 487 very influential too, while economic megatrends are weaker as they depend more on other factors.  
 488

#### 489 **4. Conclusions**

490 The exploratory scenarios describe future, plausible, and alternative situations, highlighting the  
 491 technical and socio-economic conditions that could determine them. In this article, we have built four  
 492 scenarios for BBFs to 2050, using context scenarios for the agri-food system identified in the  
 493 literature and specific drivers for BBFs identified thanks to the active contribution of stakeholders.  
 494 To validate the results, we first consulted external experts to verify the consistency of the scenarios.  
 495 Subsequently, we used the CIB method in an original way to improve the robustness of the  
 496 verification process.

497 The defined scenarios include a very advantageous situation for BBFs (BBFs on valorization path),  
 498 where the technological and socio-economic conditions are favorable to the development of an

499 efficient, well-organized, and politically supported supply chain. In a context of this type, where  
500 circularity permeates the economic system and represents a value for all citizens, a potential threat  
501 for BBFs lies in the competition in the use of the raw material, the residual biomass of the agri-food  
502 system. Conversely, in the less favorable scenario (BBFs on technocratic path), mineral fertilizers  
503 continue to dominate the market, supported by technology and public support, while a marginal BBF  
504 supply chain finds limited space in politics, hindered by powerful chemical lobbies. In the other two  
505 scenarios (BBFs on differentiation path and BBFs on polarization path), which are intermediate  
506 compared to the previous ones, the production and use of BBFs are reduced in both cases, but this  
507 situation is determined by different evolution of the drivers. In the first case, the difficulty of  
508 integrating companies and the lack of a widespread knowledge and innovation system contribute to  
509 the fragmentation of the production fabric and limit the diffusion of efficient technologies for BBFs.  
510 Their use is therefore uneven across the territory and between types of agricultural holdings. Finally,  
511 in the 'BBFs on polarization path' scenario, the production of BBFs is strongly localized in some areas  
512 where favorable conditions exist (for example, for the availability of biomass), while more generally  
513 it is hindered by various factors, such as limited environmental sensitivity and the lack of adequate  
514 technology and logistics.

515 The scenario analysis highlighted the particular importance of some drivers for the future  
516 development of BBFs, such as product quality, farmers' knowledge, adequate technology and  
517 logistics, and public intervention aimed not only at the regulation of the sector but also at the  
518 promotion of knowledge and use of BBFs, confirming what has also been found by others  
519 (Kurnawati et al., 2023). The consultation of external experts has contributed to and strengthened  
520 the coherence of the defined scenarios. However, different driver evolutions may lead to the definition  
521 of other plausible scenarios. We therefore checked whether, among all the possible scenarios  
522 generated by the BBF drivers, the scenarios presented above were also included and what the relative  
523 degree of coherence was. For this purpose, we used the CIB algorithm. This approach aims to  
524 strengthen the verification of the results of the scenario analysis as the two paths are independent and  
525 start from different assumptions. The process of building storylines ensures that the factors considered  
526 are consistent with the object of the study (in our case the BBF supply chain), since they are based  
527 on specific information combined with expert assessments and stakeholder experiences. The CIB,  
528 meanwhile, focuses on interdependent relationships between the drivers that allow any  
529 inconsistencies to be highlighted. If the results of the two techniques overlap, the risk of producing  
530 inconsistent scenarios is lower. In our case, the results of the comparison demonstrate that the  
531 scenarios built for BBFs using the EUR-Agri-SSP and the stakeholder support are included among  
532 those indicated by the CIB as consistent but also indicate how other equally plausible narratives can  
533 be generated. This outcome is not surprising when we consider that one of the characteristics that  
534 guides the choice of drivers is uncertainty (in addition to relevance) and that, the greater the  
535 uncertainty, the more numerous the possible future realizations of the driver considered will be.

536 In addition to the methodological aspect, the analysis carried out on the BBFs case study produced a  
537 further result which contributes to confirming what has already been argued (Perna, 2017) regarding  
538 the ability of scenario analysis to create/increase knowledge through comparison between actors of  
539 different origins and experiences and the debate generated during the participatory process. This  
540 knowledge goes beyond the specific object of the investigation to include the ability to project oneself  
541 into the future, an ability which, however, only a structured and continuous path can ensure. The  
542 choice of stakeholders has an impact on the entire process of construction and evaluation of the  
543 scenarios and can represent a limit, where this choice is somehow lacking not only in terms of the  
544 breadth of knowledge on the object of the research but also by the lack of forecasting skills. On the  
545 other hand, the latter can be acquired along an interactive learning path between the research group  
546 and the actors involved in the scenario analysis.

547 Ultimately, the analysis provides stakeholders (researchers, policymakers, supply chain operators)  
548 with information to evaluate possible future trends in the BBF supply chain. The drivers identified  
549 and their evolutions traced in the scenarios constitute a decision support tool for any actions to be

550 taken to favor (or hinder) the occurrence of desired (or unwanted) future situations. Monitoring the  
551 evolution of the identified drivers and constant and periodic discussion between stakeholders are the  
552 prerequisites for pursuing a desirable future development for BBFs.

747 **APPENDIX**

748 **A. List of drivers proposed by stakeholders grouped by categories.**

749 Sustainability awareness

1. Acceptance of BBF
2. Awareness of Producers (Farmers)
3. Awareness of Wastes as a Resource
4. Consolidation of Traditional Fertilisers
5. Demand of Healthy Products
6. Development of Sustainable Farming Method
7. Healthy Dietary Regimes
8. Higher Sustainability Awareness Thus Greater Demand
9. Improvement of the Landscape and of the Image of Our Agricultural Sector
10. Increase of Environmental Sensibility
11. Increased Awareness and Trust of Farmers
12. Increased Organic Production (Consumer - Export)
13. Increased Worldwide Demand for Organic Products
14. Increasing Awareness and Interest in Organic Production
15. Independence for Fertiliser
16. Public Awareness of Sustainability
17. Qualified Employment is Needed to Maintain a Sustainable Conscience
18. Raising Awareness
19. Sensibilization/Education/Promotion to Work with Alive Soils
20. Social Conscience about Use of Renewable Resources
21. Society Education about Environmental Problems Related to Agricultural Activity (Rc)

750 Political Framework

1. Administration for Farmer
2. Ban on Synthetic Fertilisers
3. Certain and Enhanced Regulation of Biomass / BBF
4. Certificates and Labels
5. Common Agricultural Policy/ Rural Development Programs
6. Compensation Measure for Soil C Sequestration
7. Design of a Common Regulation in Europe
8. Development of Regulation to Promote the Use of BBF
9. Economic Help to Develop BBF is Needed
10. Economic Sustainability Guaranteed
11. Environmental Responsive and Consistent Policies
12. Facilitation of Environmental Objectives Required by Legislation
13. Future Demands Imposed by Regulation (Water and Carbon Footprint Certifications) (Fa)
14. Influence of Lobby Groups
15. Intellectual Property Rights
16. Lack of Local Regulation
17. Lack of Political Will and Regulations to Support These Processes (Production, Distribution, Commercialization)
18. Legal Framework to be Develop
19. Legislation to Boast the Use of BBF If
20. Pressure on Transparency in the Chain
21. Protection of European Farmers Vs non-European Farmers
22. Raw Material Regulation
23. Recognition (Fps Public Health)
24. Regulation to Facilitate, Promote and Prioritize the Use of Organic Wastes to Produce BBF (Wp)
25. the Primary Sector is not Going to Lose Competitiveness
26. Variation in Specific Legislation for BBF

751 Fertilizers Market

1. Affordability of Rbff Production Process
2. Assessed Costs/Benefits of BBF
3. Competition with Other Fertilisers
4. Competitive Market Prices of BBF
5. Competitiveness of the Production Chain
6. Cost of Mineral Fertilizers
7. Cost of the Product (Including Full Production)
8. Costs of Production Will Determine Final Price of BBF
9. Decrease of the Biowaste Treatment Costs
10. Economic Imbalance of Costs of Wastes Management
11. Economic Studies Are Needed to Demonstrate Economic Profitability Growing with BBF and Alive Soils (Fa)
12. Economical Valorisation of the Food Final Products
13. Evolution of the Prices of Agricultural Products
14. High Prices of Chemical Fertilizers
15. Higher Prices of BBF in Comparison with Inorganic Fertilizers
16. Increase of Prices of Inorganic Fertilizers
17. Increase of the Price of Mineral Fertiliser
18. New Bio-Based Fertilizers Economically Viable Are Needed
19. Price of BBF: Competitive?
20. Production Costs (Competitors)
21. Qualitative Competitiveness
22. Reduction in Cost Price of BBF by Reducing Cost Price of Residual Flow
23. Remuneration of bio-based Resources
24. Valorisation Process must be Economically Sustainable

752 Technological Solutions

1. *Accessibility of Technologies*
2. *Availability of Effective Technology*
3. *Availability, Homogeneity, and Stability in Time of Fbb*
4. *BBF Ease of Use*
5. *Continuity and Volumes of Inputs*
6. *Development at Big Scale of Technologies to Reduce Costs of Production of BBF*
7. *Ease of Technology Production*
8. *Efficiency of Technologies*
9. *Enhanced BBF Processing Technology*
10. *Ensuring Consistent Quality of End Product with Changing Input*
11. *Final BBF Consistent with Characteristics of Each Production Area*
12. *Lack of Innovation and Applicable Development of Last Valorisation Processes Developed (Rc)*
13. *Local Availability of Technological Solutions*
14. *Logistic*
15. *Management Methods Viable and Suitable for Private Companies*
16. *Need for Additional Investments*
17. *New Valorisation Processes must be in Agree to the Real Situation of the Agricultural Sector (Fm)*
18. *Nitrogen Level*
19. *Preferable BBF Traits*
20. *Production of Final Stables and Homogeneous BBF*
21. *Rationalization of BBF Production Processes*
22. *Reliability (Efficiency) and Easy to Use*
23. *Reorienting Production Sites Towards BBF*
24. *Risk of Contamination in the Process*
25. *Transportation Logistics*
26. *Used of Technologies not Proven*
27. *Weakly Developed Logistics for Production and Transport*

#### 753 Innovation Uptake Process

1. *Creation of New Professional Activities*
2. *Farmers' and BBF Producers Mutual Learning and Influence*
3. *Generate the Union of the Different Actors of the Project*
4. *Importance of the Complete Supply Chain - All Components*
5. *Increasing Number of Producer Organizations That Promote the Use of Bio-Based Fertilizers*
6. *Lack of Knowledge about Waste Valorisation Technologies*
7. *Lack of Social Association Associative Willingness to Join These Initiatives*
8. *Low Technical Capacity of Actors Who have to Fuse Technique and Economy*
9. *Networking with Advisory Organizations*
10. *Occurrence of Fertilizers Producers*

#### 754 Environmental System

1. *Additional Benefits (E.G. Nutrient Input in Soil)*
2. *Assessment of Product Life Cycle Environmental Impact*
3. *Characteristics of Soils at Local Level*
4. *Greenhouse Gases*
5. *Impact of Climate Change on Soil*
6. *Improvement on Food Consumption and Yield Obtained*
7. *Nutrient Balance in Soil and Surface Water.*
8. *Optimization of Residues Management*
9. *Reduction of Vegetal Effluents*

#### 755 Bioeconomy Patterns

1. *Availability and Quality of Biomass*
2. *Boom of BBF Industry and Circular Economy*
3. *Competition in Residual Flows*
4. *Competition with Other Processing Options for Residual Flows*
5. *Increased Demand bio-based Resources*
6. *Lack of Recycling Culture*
7. *Lack of Research on Waste Characterization and Utilization*
8. *Low Availability of Sources (Different to Sugarcane) and Raw Materials*
9. *Measures Favouring Circular Economy (Green Deal)*
10. *Raw Materials (Residues) Are Readily Available*
11. *Role (Involvement) of Large Retail Chains as Waste Provider*
12. *Seasonality and Variation of Volume of Vegetable Residues Produced*
13. *Seasonality of Waste Production*
14. *Shift Towards a Circular Approach*
15. *Strength of Circular Economy*
16. *Sufficient Raw Material*

#### 756 Source: own elaboration
