31

32 Abstract

33 As sustainability concerns increasingly influence agri-food systems, environmental labels have 34 become an important tool for signalling producers' ecological responsibility to consumers. 35 However, the effectiveness of such labels depends on how they are perceived and valued in 36 specific product contexts. This study investigates consumer preferences for four environmental 37 labels in the wine sector: organic certification, carbon neutral, reduced water footprint, and reduced pesticide use. A discrete choice experiment conducted with 300 Italian wine 38 consumers, combined with latent class analysis, revealed four distinct segments with 39 40 heterogeneous responses to environmental labels. While one group rejected environmental 41 labels altogether, others displayed selective interest based on the perceived relevance of the label to specific concerns such as health or resource conservation. These findings highlight the 42 43 need for tailored communication strategies that take into account both consumers' cultural associations with wine — such as tradition, authenticity, and artisanal value — and their 44 individual priorities, including differing levels of engagement with various aspects of 45 environmental sustainability. In a category as culturally embedded as wine, where tradition, 46 identity, and quality perceptions play a central role, tailored messaging becomes especially 47 crucial to ensure that environmental-labels are understood, trusted, and valued. 48

52 **1. Introduction**

Growing environmental concerns have placed increasing attention on the role of agriculture in 53 54 climate change and the depletion of natural resources [1,2]. Viticulture exemplifies this link, 55 as it generates multiple environmental pressures through various channels, including greenhouse gas emissions, pesticide use, and water consumption. The majority of greenhouse 56 57 gas emissions in vineyard operations stem from energy use (mainly electricity and fuel) 58 required for irrigation and field work [3–7]. Additionally, in water-limited viticultural areas, irrigation can significantly increase pressure on local water supplies and contribute to the 59 overall environmental footprint [8]. Moreover, due to the susceptibility of grapevines to fungal 60 diseases, viticulture ranks among the sectors with the highest pesticide use per hectare in 61 Europe [9,10]. This dependency raises concerns related to biodiversity, soil health, and the 62 contamination of water bodies, thus prompting interest in more sustainable practices, such as 63 low-input strategies and integrated pest management [11,12]. Given these combined pressures, 64 viticulture provides a compelling case for examining sustainability transitions both for its 65 environmental challenges and its strong connections to local economies, cultural heritage, and 66 rural identity [8,12]. In many wine-producing regions, vineyards are more than a source of 67 agricultural output, they shape landscapes, support tourism, and contribute to the symbolic and 68 economic value of entire territories. These ties are further reinforced by the fact that wineries 69 are often small, locally embedded enterprises, deeply integrated into the social and economic 70 71 fabric of rural areas. This territorial relevance makes viticulture especially visible and politically salient in sustainability debates [4,6]. 72

73 Sustainability in viticulture is influenced by a range of conflicting factors. Producers must 74 balance the need to maintain grape quality and economic viability, while consumers demand 75 environmentally responsible products without compromising on taste or price. Meanwhile, public policies promote stricter environmental standards and regulations. At the European 76 77 level, the Common Agricultural Policy (CAP) and the Farm to Fork Strategy encourage the 78 adoption of environmentally sustainable farming practices. At the national level, initiatives 79 such as France's Haute Valeur Environnementale (HVE) certification and Italy's National 80 Quality System for Integrated Production (Sistema di Qualità Nazionale Produzione Integrata, 81 SQNPI) encourage producers to meet specific ecological benchmarks and reduce chemical 82 inputs. These initiatives not only drive sustainable practices at the production level but also support transparency through signals of environmental sustainability. In this context, 83 84 environmental labels have become a key tool for communicating the sustainability attributes of a product whether by indicating reduced impacts, such as lower water consumption or
pesticide use, or by highlighting contributions to ecosystem services, such as carbon
sequestration [13,14].

88 As consumers become more environmentally conscious, they are increasingly drawn to products that carry environmental labels. However, despite this growing interest, consumer 89 90 responses to sustainability claims are not uniform. Delmas and Gergaud [15] highlight that reactions to environmental labels can vary considerably. This may be due to the proliferation 91 92 of labelled products in the marketplace, which can lead to information overload [16,17], or to concerns about potential trade-offs between environmentally friendly practices and product 93 quality [18,19]. Indeed, some studies show that environmentally certified wines may be 94 perceived as lower in sensory quality, or that consumers struggle to distinguish between 95 96 different types of labels [20].

The coexistence of various types of environmental labels, ranging from broad sustainability 97 98 claims to indicators focused on single issues, further complicates consumer interpretation. While some labels, such as organic certification, are often associated with a holistic approach 99 to sustainability, they may not explicitly address all environmental dimensions (e.g., 100 greenhouse gas emissions or water use). Conversely, labels like "carbon neutral" focus on 101 102 specific impacts but do not account for other aspects such as pesticide use or biodiversity. This 103 divergence can lead consumers to perceive fundamentally different sustainability efforts as 104 interchangeable [21,22]. In this context, the credibility, familiarity, and clarity of environmental labels become decisive for consumer acceptance. Yet, as Schäufele and Hamm 105 [23] point out, such qualities are often lacking in the wine sector, where label meanings and 106 standards are not always well understood [24]. 107

In Italy, while labels highlighting specific positive impacts on natural resources are not yet 108 109 widespread or standardised, they are beginning to emerge, particularly through private 110 initiatives and pilot projects, reflecting a growing interest in communicating differentiated 111 environmental performances to consumers [25]. Understanding how these labels are perceived can help producers tailor their sustainability strategies and allow policymakers to design clearer 112 113 and more targeted communication tools. It also sheds light on the specific environmental 114 concerns that matter most to consumers, offering practical insights into the drivers of their 115 purchasing decisions and helping to align supply-side initiatives with real demand.

116 Building on this premise, the present study explores how consumers perceive different types 117 of environmental labels and how these perceptions influence their preferences in the wine 118 sector. Four labels were selected to reflect distinct dimensions of sustainability: organic 119 certification, carbon neutrality, reduced water footprint, and reduced pesticide use. Extending 120 previous research such as Tait et al. [26], who examined preferences for sustainable wine 121 attributes in Californian Sauvignon blanc and emphasised the relevance of specific 122 environmental outcomes, our study applies a discrete choice experiment to the Italian context. 123 While organic certification is well established in Italy, labels referring to more targeted environmental impacts such as carbon emissions, water use, or pesticide application remain 124 125 relatively less familiar to consumers and less embedded in their purchasing routines. This context, where wine production is deeply rooted in cultural practices and heritage values, 126 127 provides a novel perspective for examining how consumers interpret differentiated sustainability claims in a product category shaped by tradition and identity. 128

In this setting, we adopt a latent class approach to understand how different environmental labels are perceived, uncovering the diversity of consumer reactions to sustainability claims and offering insights into how environmental messaging can be effectively tailored. This paper is structured as follows: the following section presents the methodology employed and the econometric analysis. The subsequent sections report the results, followed by a discussion and concluding remarks, presented in two distinct parts.

135

136 **2.** Methodology and econometric analysis

137 2.1 Survey design

The data were collected through an online questionnaire administered via Google Forms, structured into five consecutive sections covering respondent eligibility, wine consumption behaviours, motivations underlying preferences, and both psychographic and sociodemographic profiling.

More specifically, the section included three filter questions. The first filter excluded individuals who were not responsible or co-responsible for food purchases within their family, ensuring that participants were involved in purchasing decisions. The second filter focused on the frequency of wine consumption, to ensure that only individuals who consumed wine regularly (at least once a month) were included. Those who never consumed wine or drank it 147 less than once a month were excluded. The third filter concerned the price range at which individuals usually purchase wine for domestic consumption. We excluded those who typically 148 149 spent more than 14.99 € per bottle, as the study aimed to focus on wines purchased for routine 150 consumption, within a price range of $4 \in$ to $14 \in$. While wine prices can vary significantly, with 151 some wines exceeding 14 €, this decision aligned with the average monthly wine expenditure per family, which is $11.43 \in [27]$, and the average price of a bottle with a designation of origin, 152 153 which is $5.40 \in [28]$. As a result, the respondents who participated in the study were those involved in food purchasing decisions, consumed wine regularly, and spent an amount 154 155 consistent with the average for routine wine consumption.

156 The second section presented consumers with a discrete choice experiment (DCE), which will

157 be described in detail in Section 2.2.

In the third section of the questionnaire, consumers were asked to choose their preferred labelfrom the four options and to explain the reasons behind their choice.

The fourth section aimed to assess the psychographic characteristics of the sample in order to 160 explore potential correlations with their preferences. Existing literature highlights the role of 161 sustainability awareness in shaping sustainable food choices [29,30]. To measure this 162 dimension, we employed the Involvement in Sustainable Eating (ISE) scale developed by 163 Pieniak et al. [31] and adapted by Van Loo et al. [32]. Linked to this aspect, we evaluated how 164 consumers perceive the impact of their choices on the future, using the scale on the 165 Consideration of Future Consequences (CFC), developed by Joireman et al. [33]. Finally, 166 167 assessed the extent to which individuals attribute responsibility to themselves when making sustainability-related choices, utilising the Ascription of Responsibility (AOR) scale [34,35]. 168 169 All three constructs were measured using five-point Likert scales ranging from 1 (completely disagree) to 5 (completely agree). This range was chosen to ensure consistency, as both the 170 171 CFC and ISE are originally measured on a 1-to-5 scale, and the AOR scale was consequently 172 adapted. Table 1 presents the items included in each scale, along with key descriptive statistics 173 and Cronbach's α , which exceeds the minimum threshold of 0.70, indicating satisfactory 174 internal consistency and reliability.

Table 1. Items from the three psychographic scales in the questionnaire along with their respective descriptive statistics (analysis performed using STATA/SE 18.0).

Scale (Alpha)	Item	Mean	Standard deviation	Source
Consideration of future	My behaviour is generally influenced by future consequences	3.26	1.26	Joireman et al, 2012
consequences (0.83)	When I decide to consume food products, I think about the future consequences of my decision	3.40	1.32	
	I prefer foods that make me feel better in the future to foods that satisfy me here and now	3.34	1.25	
	I often think about negative outcomes of the food I consume even if the negative outcome will not occur for many years	3.43	1.36	
Involvement in sustainable	Sustainable eating is very important to me	3.61	1.14	Pienak et al., 2010:
eating (0.94)	I care a lot about sustainable eating	3.35	1,12	Van Loo et
	Sustainable eating means a lot to me	3.43	1.16	al., 2017
	I am very concerned about the consequences of what I eat in terms of sustainability	3.43	1.16	
Ascription of	I feel personally responsible for the			Abrahamse
responsibility	problems resulting from my non-	3.16	1.29	et al., 2011
(0.90)	My non-ecofriendly purchases contribute to environmental problems	3.46	1.27	
	environmental problems	3.43	1.23	

177 The fifth and final section of the questionnaire aimed to gather the primary sociodemographic

178 characteristics of the sample.

179

180 2.2 Experimental design

The DCE allows comparing a discrete number of alternatives differentiated by the levels 181 characterising the different attributes of the product. Widely acknowledged in the literature as 182 183 an effective and intuitive tool, the DCE is capable of readily capturing consumer preferences 184 [36]. Specifically, we asked respondents to imagine themselves at the place where they usually 185 buy wine, with the intention of purchasing a Bordeaux-style bottle of red wine for a regular 186 meal at home. We then asked them to choose between two products or to opt for the no-choice 187 option if neither satisfied their preferences. The base wine selected for our scenarios was a 188 Sangiovese IGT, produced and bottled in Italy (San Casciano, Tuscany, in the Chianti Region) 189 with an alcohol content of 13%. We know from the literature that the grape variety and the 190 origin are fundamental characteristics in the choice of the wine [37-39]. Therefore, we opted 191 for Sangiovese due to its widespread cultivation throughout Italy, making it one of the nation's 192 most significant and emblematic grape varieties. Furthermore, we chose San Casciano because 193 it is a locality renowned for its strong association with winemaking [40,41]. We centred the 194 analysis on two attributes: price and environmental label (Table 2). As outlined in the introduction, our analysis focused on three key sustainability aspects that environmental labels 195 196 can signal — water use, pesticide use, and carbon footprint [8–12] — comparing them with the most widespread environmental label on the market, organic certification, and with the absence 197 of any label. While labels addressing specific environmental dimensions (e.g. "carbon neutral" 198 or "reduced water footprint") have begun to emerge in various markets [25], none of them is 199 yet consolidated or widely recognised by consumers in the Italian context. The environmental 200 201 labels tested were kept general by design, in order to reflect their current state of development and limited standardisation in the Italian market. The price levels were selected based on 202 market research: the minimum level was set just below the average price of a bottle with a 203 designation of origin, while the maximum level corresponded to the cut-off point used in our 204 sample selection criteria for everyday wine consumption [27, 28]. Figure 1 displays the 4 labels 205 206 used for the different levels.

207 <u>Table 2. Attributes and their corresponding levels in the DCE.</u>

208

Figure 1. The 4 environmental labels employed in the choice experiment.

Once attributes and levels were chosen, we implemented a pilot study involving a sample of 50 wine consumers. Then, we created an efficient design using Ngene software (ChoiceMetrics Ltd.), constructed based on the priors obtained through a pilot study (as suggested by [42]). To minimise respondents' fatigue in order to ensure their engagement until the end of the survey, each participant was exposed to five choice sets. The sample was randomly divided into two blocks to maintain variation and balance in presentation.

216 Figure 2. Example of a choice set.

217

218 2.3 Econometric model and Latent Class Analysis

219 Discrete Choice Models derive from McFadden's Random Utility Theory [43] and Lancaster's 220 [44] consumer studies. Their theoretical framework posits that a consumer tends to act 221 rationally by choosing among various market options the one that provides them with the 222 maximum utility. Simultaneously, the utility of a good is the result of the characteristics that 223 the good possesses. Therefore, the utility U that individual *i* obtains by opting for alternative *n* 224 in a choice set *k* is:

225
$$U_{ink} = \boldsymbol{\beta}' \mathbf{X}_{ink} + ASC + \varepsilon_{ink}$$
(1)

In Equation 1, β' represents a vector of coefficients encompassing the impact of each level X_{ink} of every attribute on the utility function. The term ASC (Alternative Specific Constant) is a constant that encapsulates all the product characteristics present in the scenario but not considered within the experimental design (serving as the baseline image). ε_{ink} is the stochastic component of utility, identically and independently distributed. In our study, during data
processing the price was considered a continuous variable, while the environmental labels were
treated as categorical variables.

Based on these assumptions, the probability (Equation 2) of choosing a product in a scenario is linked to the utility that the option has compared to the other options [45]. Therefore, it is the ratio between the deterministic component of the utility of alternative n and the sum of the deterministic component of the utility of all the possible alternatives.

$$237 \quad Pr_{in} = \frac{e^{\beta' X_{in}}}{\sum_{1}^{K} e^{\beta' X_{ik}}}$$

238 X_{in} represents the vector of the attributes for individual *i* for alternative *n*, while X_{ik} is the same 239 vector for alternative *k*.

Given the assumption of heterogeneous consumer preferences [46–48], we applied Latent Class Analysis (LCA) to analyse the DCE data. LCA enables the identification of distinct latent classes based on individual response patterns. The analysis was conducted using Latent Gold Choice 4.5 (Statistical Innovation Inc.).

To profile the identified classes, we employed Chi-squared Automatic Interaction Detection 244 245 (CHAID) analysis, which performs chi-squared tests to assess whether class membership is significantly associated with selected variables. In our study, the dependent variable was class 246 membership as defined by the latent class analysis. CHAID was used to explore class 247 differences across a set of psychographic, sociodemographic, and behavioural variables, and 248 served as the basis for describing class profiles. Although CHAID does not imply causal 249 250 relationships or offer predictive power, it provides a robust exploratory framework for 251 interpreting latent class structures and identifying the variables that most clearly differentiate one segment from the others. Data processing was conducted using SICHAID Define (version 252 253 4.0.5.18305)

254

255 2.4 Sample description

The survey was disseminated to a sample of Italian consumers across various social platforms from November 2023 to January 2024. Out of the 437 Italians who initially agreed to participate in our questionnaire, 56 were excluded as they were not responsible for food purchases, and an additional 47 declared never consuming wine. After this screening, the remaining 334

(2)

consumers were considered. Among them, 34 reported purchasing wine for more than 14.99 €
per litre. Consequently, our final sample consisted of 300 consumers (Table 3). The sample is
well-distributed by gender and includes participants from a broad age range. When it comes to
wine consumption, our sample primarily spends between 5 and 10 euros on a Bordeaux bottle
for regular home consumption, and, additionally, 88% of respondents stated consuming wine
more than once a month, with one-third of the sample consuming it at least once every two
days.

Table 3. Sociodemographic and behavioural traits related to wine in the sample of 300 Italianconsumers who took part in the DCE.

Variable	Sample (%)	
Gender		
Male	144 (48%)

269

270 **3. Results**

271 *3.1 Discrete choice experiment and latent class analysis*

To choose the best model for our analysis, we explored different options with varying numbers of latent classes. Based on the Bayesian Information Criterion (BIC), which balances model fit and complexity, the 4-class model was selected, as it showed the lowest BIC value, while also ensuring the interpretability and significance of parameters [49,50] (Table 4).

276	Table 4. The tested models with their respective parameters. The highlighted model is the one
277	chosen for the LCA.

Number of classes	LL	BIC	Npar	\mathbb{R}^2
1	-1516	3067	6	3%
2	-1382	2838	13	19%
3	-1324	2762	20	37%
<u>4</u>	<u>-1289</u>	<u>2732</u>	<u>27</u>	<u>44%</u>
5	-1271	2737	34	51%
6	-1256	2746	41	53%
7	-1241	2756	48	58%

278 Note: LL represents log-likelihood, BIC stands for Bayesian Information Criterion, and N.
279 Par denotes the number of parameters.

280 The β coefficients related to the utility function are presented in Table 5. As for the size of the

classes, the first class includes 35% of the sample, the second 30%, the third 24%, and the

282 fourth 11%.

Note: *indicates a significance of 90%, **of 95%, and ***of 99%. For the *label* attribute, the
 reference category is the absence of any environmental label.

For Class 1, the price of wine does not pose a barrier, at least up to 14 €, which is the highest 286 price point in our experiment. Conversely, all four environmental labels create disutility for 287 these consumers, who prefer a bottle without such characteristics. Class 4 also diverges from 288 the environmentally oriented segments, but does so by predominantly opting for the no-choice 289 290 alternative—indicating limited engagement with the product options overall. Classes 2 and 3, by contrast, share similarities, as both show a preference for wines with an environmental label. 291 292 While differences emerge in the relative importance attributed to price — higher for Class 2 293 than for Class 3 — a clearer understanding of their preferences can be gained by examining 294 how each class evaluates the environmental labels included in the experiment. To this end, we analysed the distribution of preferences across the four labels for Classes 2 and 3. The results, 295 296 shown in Figure 3, illustrate the relative importance attributed to each label.

Figure 3. Relative importance of different environmental labels in classes 2 and 3.

As shown in Figure 3, Class 2 assigns greatest importance to labels indicating reduced water footprint and reduced pesticide use, while organic certification is considered less relevant, and carbon neutrality is the least valued. In contrast, Class 3 places highest importance on organic wine, followed by reduced pesticide use and carbon neutrality. The label referring to reduced water footprint receives the lowest importance in this class.

To better understand the underlying reasons behind the preference for environmental labels in 304 Classes 2 and 3 (i.e., the two segments showing positive utility for environmental labels in the 305 DCE) we analysed responses to a follow-up question included in the third section of the 306 questionnaire. After completing the choice tasks, participants were asked to select their 307 preferred label among the four options and indicate up to three reasons for their choice. For 308 309 each class, we calculated the relative frequency of each reason by dividing the number of times 310 it was selected by the total number of responses given for that label. The results are presented in Table 6. Data for Classes 1 and 4 are not included, as Class 1 tended to avoid labelled wines, 311 312 while Class 4 showed general indifference.

Table 6. Reasons why consumers preferred a particular label over others. Each respondent could specify up to 3 motivations. The data were collected in the third section of the questionnaire, where participants were asked to indicate their favourite environmental label and the reasons behind their choice.

Cross-referencing the information from Figure 3 and Table 6 offers more specific insights into 318 these two classes. Following the preference ranking expressed in the DCE, the reduced water 319 footprint label, along with the reduced use of pesticides, emerges as most valued in Class 2. 320 321 The preference for the reduced water footprint label appears to be driven primarily by a specific concern for this issue, followed by its perceived personal relevance and, to a lesser extent, a 322 323 broader attention to sustainability. The preference for reduced pesticide use is particularly 324 linked to health motivations. The organic certification, third in importance, is primarily 325 appreciated for the trustworthiness of the certification scheme and for concern with pollution 326 reduction as a specific issue. Finally, the carbon neutral label, although the least preferred, still 327 gains support due to a perceived connection with the issue of emissions, personal relevance, 328 and general sustainability awareness.

329 Class 3, with a strong preference for organic certification, favours this label primarily due to 330 the trust placed in the certification scheme. The reduced pesticide label is also appreciated, 331 primarily for health-related motivations. Preferences for the carbon neutral label reflect a 332 combination of concern about emissions and broader sustainability considerations. The reduced 333 water footprint label, although less central, is valued by some respondents due specific 334 awareness of the issue and its perceived personal relevance.

335 *3.2 Profiling*

Table 7 reports the characteristics that were found to be significant in the CHAID analysis (AOR, age, usual spending on wine for domestic consumption, and frequency of wine consumption at home). The analysis was conducted for each class, aiming to understand the variables that distinguish each cluster from the rest of the sample. Finally, Table 8 illustrates how the variables reported in Table 7 distinguish the different classes.

now the variables reported in Table 7 distinguish the different classes.

Table 7. The variables identified as significant in the CHAID analysis. For each class, thevariables that distinguish them significantly from the rest of the sample are listed.

Class	Variable	LR Chi-Squared	df
Class 1	Ascription of responsibility**	8.16	1
Class 2	Age**	10.62	1
	Usual spending on wine consumed at home***	25.48	2
Class 3	Usual spending on wine consumed at home***	9.34	1
Class 4	Frequency of wine consumption at home***	9.55	1

- 343 Note: the sociodemographic, behavioural, and psychographic variables that are not statistically
- significant are not included in the table. **indicates a significance of 95%, and ***of 99%.

Table 8. Profiles of latent classes. 345 Class Variable Class 1 Low-Responsibility Consumers – 35% Ascription of responsibility Class 1 Others Total Medium-low 43% 57% 152 High 27% 73% 148 Class 2 Budget-Conscious Young Adults - 30% Age Class 2 Others Total Under 33 42% 58% 100 Over 33 24% 76% 200 Usual spending on wine consumed at home Under 5€ 49% 51% 90 Over 5€ 19% 81% 210 Class 3 Higher-Spending Wine Buyers – 24% Usual spending on wine consumed at home Class 3 Others Total Under 5€ 13% 87% 90 Over 5€ 28% 72% 210 Class 4 Frequent Wine Drinkers – 11% Frequency of wine consumption at home Class 4 Others Total Less than once a week 97% 3% 88 At least once a week 14% 86% 212

Note: For clarity, the underlined values highlight the variables through which each class differs
most markedly from the rest of the sample. Percentages are to be read row-wise and should be
interpreted in relation to the overall size of each class. For example, in Class 1 — which
represents 35% of the total sample — having 43% of respondents with medium-low Ascription
of Responsibility indicates a prevalence of this trait within the group.

351

Class 1, which shows a preference for wines without environmental labels, includes consumers who report lower levels of responsibility attribution for the environmental impact of their choices. Class 2 is primarily composed of individuals under the age of 33 who typically spend less than \in 5 per bottle for everyday wine consumed at home. Class 3 is similarly defined by wine expenditure, but in the higher range — consumers who usually spend more than \notin 5 per bottle. Lastly, Class 4, identified by the frequent selection of the no-choice option in the DCE, predominantly includes respondents who drink wine on a daily basis.

359

360 **4. Discussion**

The results highlight how environmental labels in the wine sector are perceived in ways that 361 vary markedly across consumers, reflecting different priorities, cognitive filters, and 362 363 expectations. Class 1, representing a substantial share of the sample, actively rejects environmental labels: the negative and significant coefficients in the utility function indicate 364 that the presence of a label reduces product appeal. This suggests that, for these consumers, 365 environmental labels may be perceived not simply as irrelevant, but as a disruption to the 366 perceived authenticity of the wine. This is particularly relevant in the wine sector, where 367 conventional practices that often involve chemical inputs are culturally associated with sensory 368 quality and artisanal expertise. As noted by Delmas and Lessem [20], environmental label can 369 370 conflict with quality expectations when they are seen as departing from tradition. In this 371 context, environmental messaging might be interpreted as a signal of lower quality or as an ideological intrusion [51]. Communication strategies targeting this segment may therefore 372 373 benefit from avoiding polarising framings (e.g., conventional vs. sustainable) and instead seek 374 to embed sustainability within familiar narratives, for example by presenting reduced pesticide 375 use as a means of enhancing terroir expression and preserving traditional know-how [52].

Class 2 adopts a more pragmatic, issue-oriented perspective. These consumers, who are mostly
younger and more price-sensitive, seem to evaluate environmental labels based on their
perceived relevance to tangible issues, such as personal health or the protection of specific

379 resources, rather than on broader ideological or abstract commitments. This may reflect the fact that younger generations have long been bombarded with sustainability-related messages, 380 381 which could have contributed to a more pragmatic approach to such topics. It is possible that they view organic certification not as a response to a clearly defined environmental concern, 382 383 but rather as a broad sustainability claim shaped by marketing language. Such evidence aligns 384 with Schäufele and Hamm [23], who observe that younger consumers are not indifferent to 385 sustainability, but need clear, targeted information to activate their interest and guide their 386 choices. Similar results were obtained by Moscovici et al. [53]. This interpretation may also help explain why, in our results, organic certification was not particularly appreciated by this 387 group: despite its environmental intentions, the label does not explicitly communicate specific 388 benefits. As noted by Anagnostou and colleagues [54], the findings suggest that labels must 389 clearly convey their specific environmental benefits to be valued by more pragmatic 390 391 consumers. Communication strategies here should prioritise transparency, through direct and concise formats such as infographics or short claims, explicitly linking the label to specific 392 benefits. Health-related concerns and the perceived relevance of water-related issues emerge 393 as particularly effective drivers of interest in this group. 394

In contrast, Class 3 shows a clear preference for organic certification, which appears to be 395 396 chosen primarily because it is considered trustworthy. While this preference seems to be driven 397 by the perceived credibility of the label, our findings resonate with observations by Schäufele 398 and Hamm [23], who suggest that, when consumers trust organic certification, it can also serve as a signal of quality. In this light, it is possible that, for this group, organic certification is seen 399 400 not only as a marker of environmental responsibility but also as an indicator of overall product reliability or value. Communication strategies should therefore aim to reinforce this trust—by 401 402 highlighting long-standing engagement with sustainability (e.g., "since 2010 we've worked to 403 reduce our environmental impact") and by integrating organic certification within a broader set 404 of recognised quality cues. These might include official designations of origin or endorsements 405 such as awards and scores from reputable wine guides, which can contribute to a coherent and 406 trustworthy product profile.

407 Lastly, Class 4, composed of frequent wine consumers, shows a marked tendency to opt for the 408 no-choice alternative. The negative and significant constant associated with this option 409 suggests that the wines presented in the experiment, regardless of their environmental labels, 410 often failed to meet the expectations of these consumers. This may indicate that frequent 411 drinkers tend to rely on well-established preferences and are oriented toward wines they already 412 know and feel confident choosing. Their decision-making appears to be driven by the pursuit of a wine that delivers a satisfying taste at a reasonable price, rather than by interest in new 413 414 sustainability attributes. In this context, environmental labels do not actively influence 415 preferences, not necessarily because of opposition, but because they are not salient in the 416 evaluation process. This finding resonates with previous studies that identify frequent wine 417 drinkers as less susceptible to environmental label influence, unless such labels are strongly 418 associated with trusted brands or quality cues [20]. Communication efforts aiming to reach this segment might therefore benefit from showing how sustainability can contribute to maintaining 419 420 product quality and price accessibility rather than positioning it as an added or separate value.

421 Overall, these findings confirm that environmental labels are not universally interpreted nor uniformly influential. Their impact depends on how well they resonate with consumers' 422 concrete concerns and decision-making logics, whether related to trust in the certification 423 system, concerns about health, established consumption habits, or sensitivity to specific 424 425 environmental issues. While some consumers appreciate environmental labels as a sign of 426 credibility, others value them for addressing specific concerns such as pesticide use or water 427 conservation, while others still disregard them altogether, seeing them as irrelevant or even at odds with their perception of what constitutes a "good wine". This reinforces the idea, 428 429 supported in recent literature, that sustainability in wine is not a simple binary attribute but interacts with the symbolic, emotional, and contextual layers of consumer experience [23]. 430 431 Recognising these differences is essential to avoid reductive assumptions, such as expecting all consumers to respond similarly to the same label [54], and to develop communication 432 433 strategies that are attuned to the diversity of decision criteria that shape wine consumption. Rather than assuming uniform sensitivity to sustainability, it becomes necessary to 434 435 acknowledge that wine remains a deeply cultural and experiential product, where tradition, 436 pleasure, routine and expectations coexist in complex ways [55].

437

438

5. Conclusions

This study investigated how different environmental labels — organic, carbon neutral, reduced water footprint, and reduced pesticide use — are perceived by wine consumers and how they influence purchase preferences. Using a discrete choice experiment combined with latent class analysis, we identified four distinct consumer segments, each characterised by different sensitivities to environmental labels.

The results reveal that environmental labels do not have a uniform effect across the sample. 444 For a significant portion of consumers, environmental labels reduce the perceived utility of the 445 product, suggesting a potential tension between sustainability messaging and traditional 446 447 expectations in wine. Others evaluate labels based on their perceived relevance to specific concerns, such as pesticide exposure or water conservation, while another group places 448 449 particular value on organic certification, appreciating it for its reliability. A final segment 450 shows limited responsiveness to any of the proposed alternatives, as indicated by a significant tendency to opt for the no-choice option, a behaviour that likely reflects reliance on habitual 451 452 choices and a lack of interest in unfamiliar cues.

These findings underline the importance of tailoring sustainability communication to different interpretive frameworks. Labels are not neutral signals, but are filtered through existing beliefs, priorities, and heuristics. Clear, differentiated, and context-sensitive communication is therefore essential not only to enhance label effectiveness, but also to avoid misunderstandings about what each label actually conveys.

For producers and policymakers, this suggests that the success of sustainability initiatives in the wine sector depends not only on improving environmental performance, but also on fostering more nuanced forms of engagement with consumers: acknowledging the plurality of motivations that shape wine choices, and the cultural and experiential nature of the product itself.

While the study offers relevant insights into how consumers interpret different environmental 463 464 labels in the wine sector, some limitations also point to productive directions for future 465 research. As with any stated preference method, the discrete choice experiment relies on a 466 hypothetical setting. Future studies could explore how preferences observed here translate into actual purchasing behaviour. Moreover, the environmental labels tested were kept general by 467 468 design, in order to reflect their current state of development and limited standardisation in the 469 Italian market. Future work may investigate how consumer preferences vary when labels are 470 framed with more detailed wording, design elements, or institutional endorsements. Finally, 471 while our findings are grounded in the Italian context, they open avenues for cross-national 472 comparisons aimed at understanding how cultural heritage interacts with sustainability 473 perceptions in other wine-producing countries.
